

Phase Equilibrium

C = 3: Ternary Systems:

Example 1: Ternary Eutectic

Di - An - Fo

Adding components, becomes increasingly difficult to depict

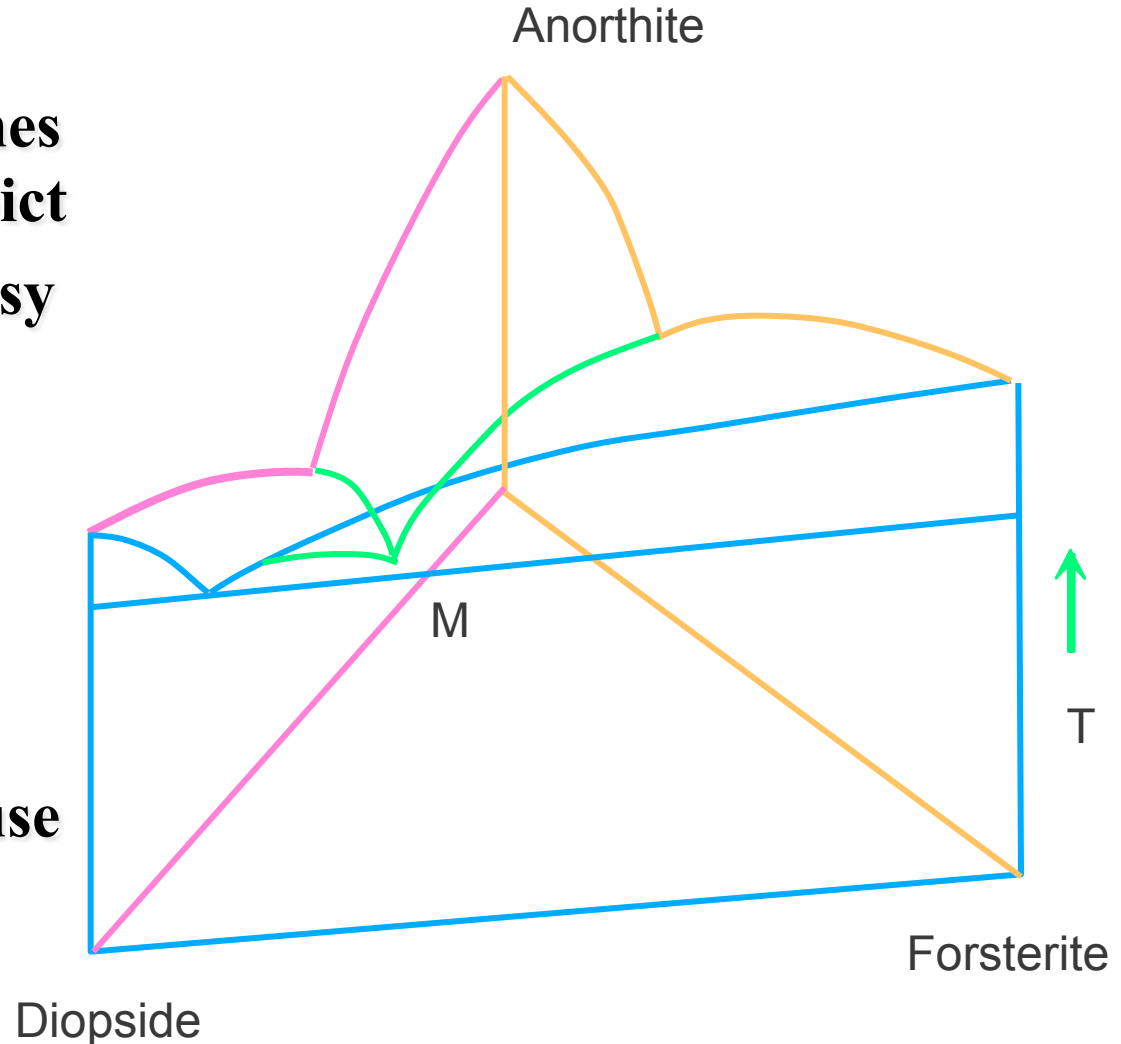

◆ 1-C: P - T diagrams easy

◆ 2-C: isobaric T-X, isothermal P-X...

◆ 3-C: ??

▲ Still need T or P variable

▲ Project? Hard to use as shown

C = 3: Ternary Systems:

Example 1: Ternary Eutectic

Di - An - Fo

Note three binary eutectics

No solid solution

Ternary eutectic = M

T - X Projection of Di - An - Fo

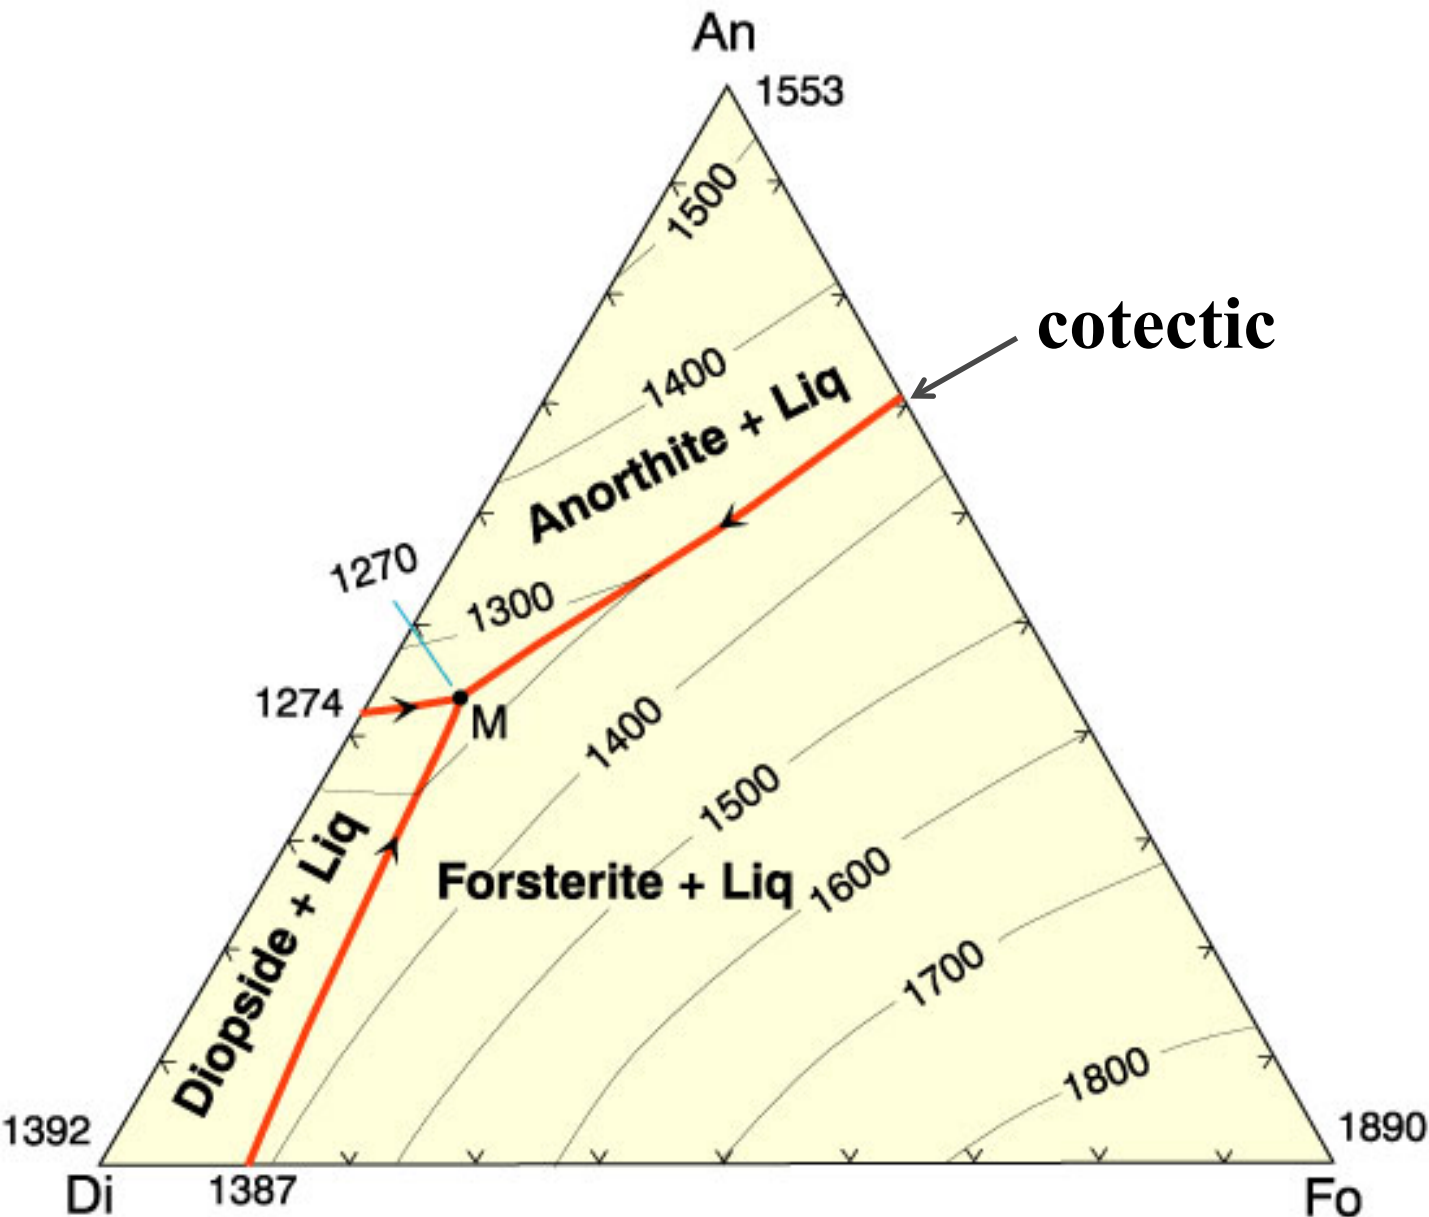

Figure 7.2. Isobaric diagram illustrating the liquidus temperatures in the Di-An-Fo system at atmospheric pressure (0.1 MPa). After Bowen (1915), A. J. Sci., and Morse (1994), Basalts and Phase Diagrams. Krieger Publishers.

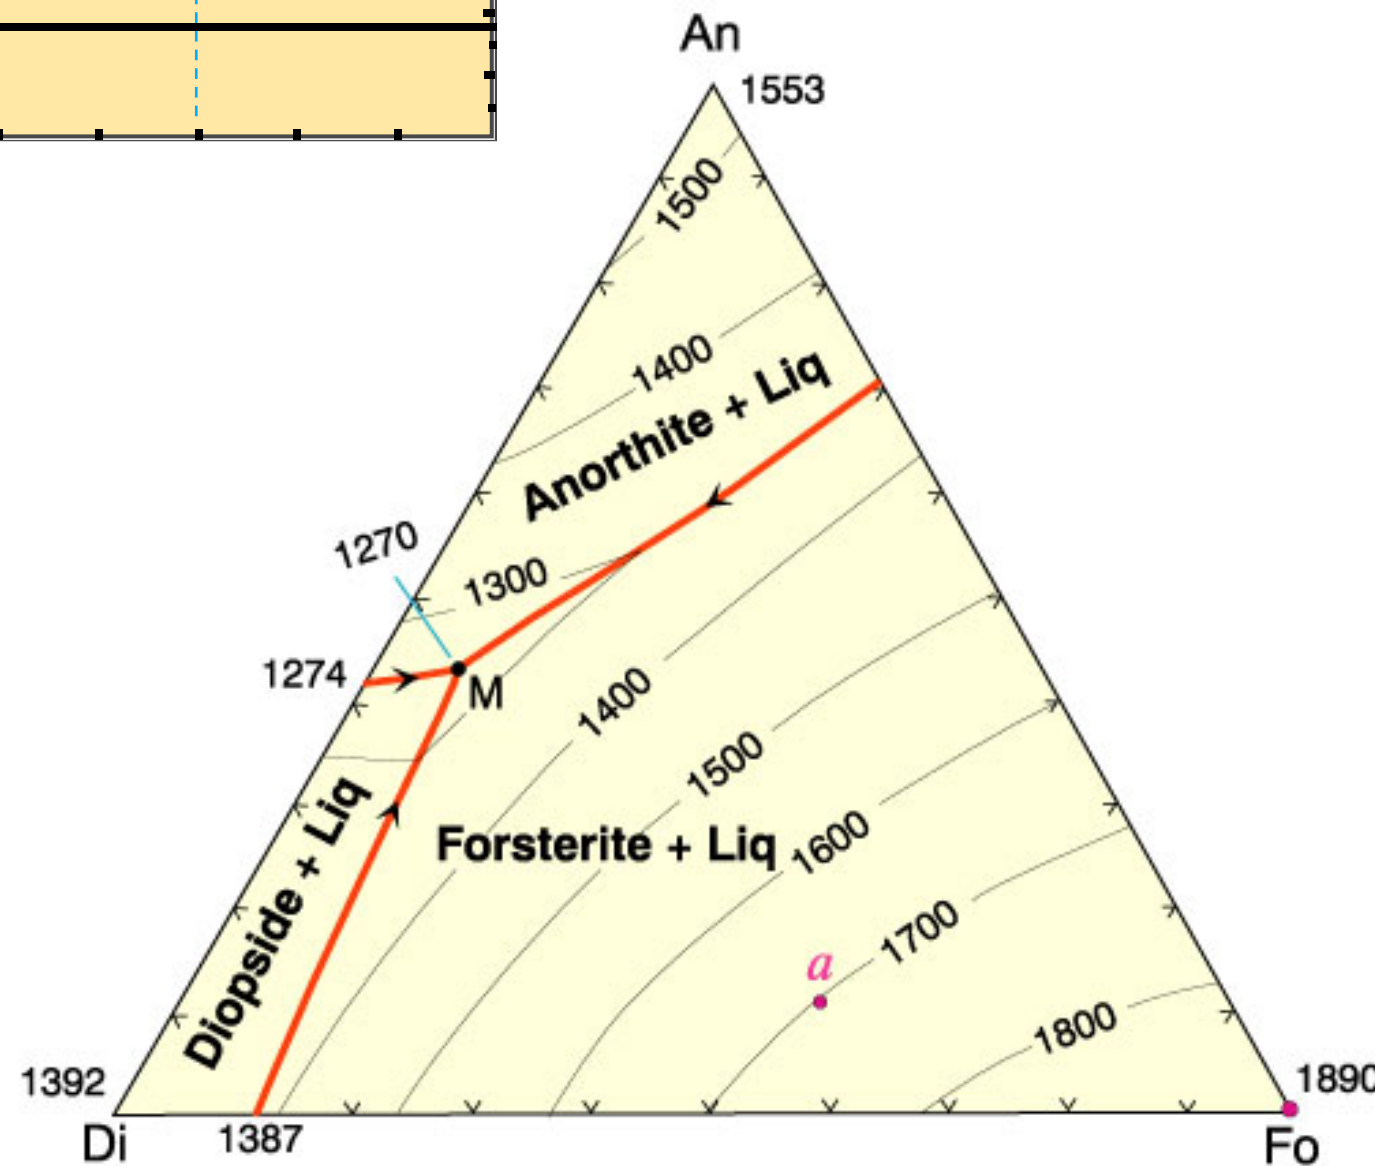

Crystallization Relationships

Pure Fo forms
Just as in binary

$\phi = ?$
 $F = ?$

◆ $\phi = 2$ (Fo + Liq)

◆ $F = 3 - 2 + 1 = 2$

If on liquidus, need to specify only 2 intensive variables to determine the system

◆ T and $X_{\text{An}}^{\text{liq}}$ or

◆ $X_{\text{An}}^{\text{liq}}$ and $X_{\text{Fo}}^{\text{liq}}$

X of pure Fo is fixed

Continue to cool;

◆ Fo crystallizes and liquid loses Fo component

◆ X_{liq} moves directly away from Fo corner

◆ “Liquid line of descent” is a -> b

Along this line liquid cools from 1700°C to about 1350°C with a continuous reaction:

What happens next at 1350°C ?

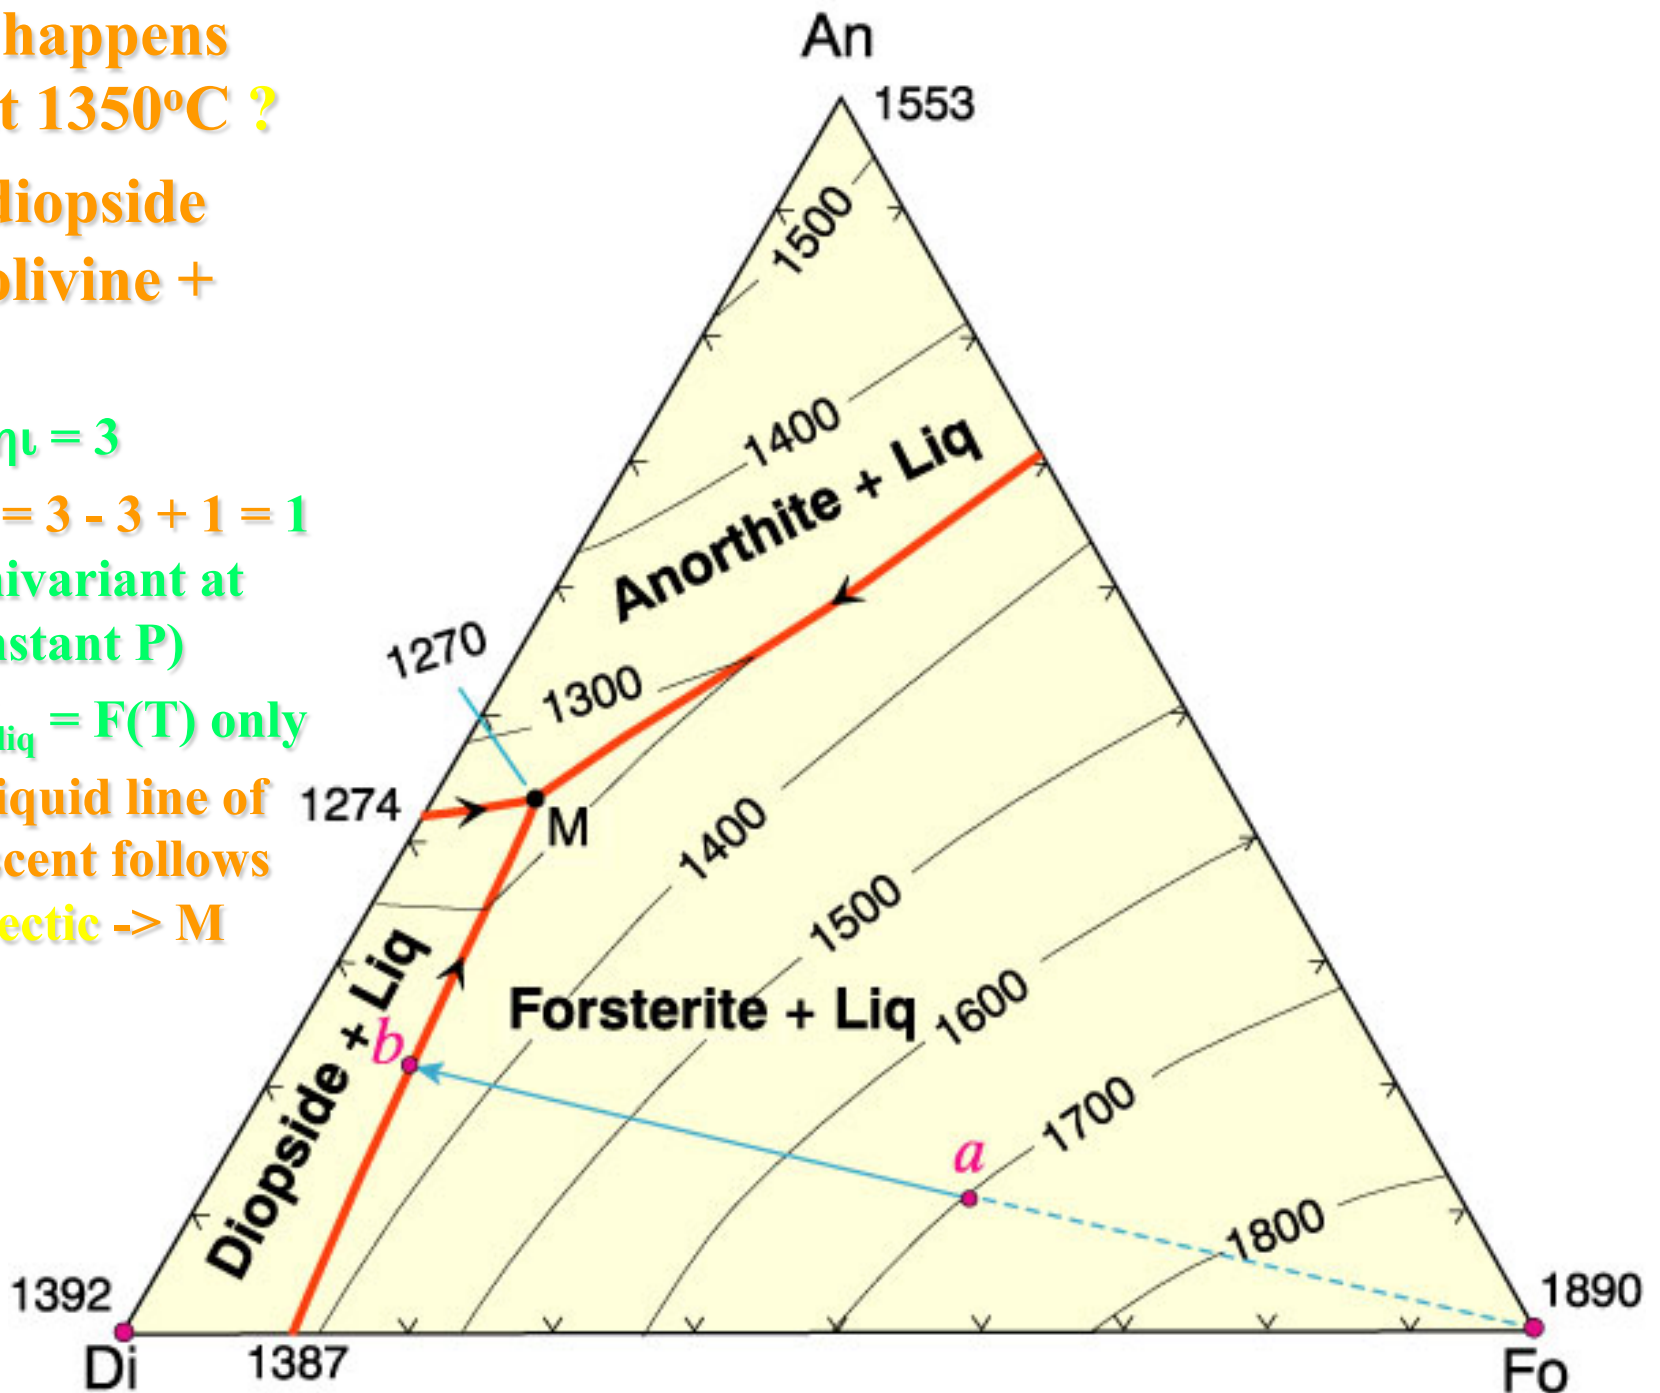

Pure diopside joins olivine + liquid

◆ $\pi_{\eta} = 3$

◆ $F = 3 - 3 + 1 = 1$
(univariant at constant P)

◆ $X_{\text{liq}} = F(T)$ only

◆ Liquid line of descent follows cotectic \rightarrow M

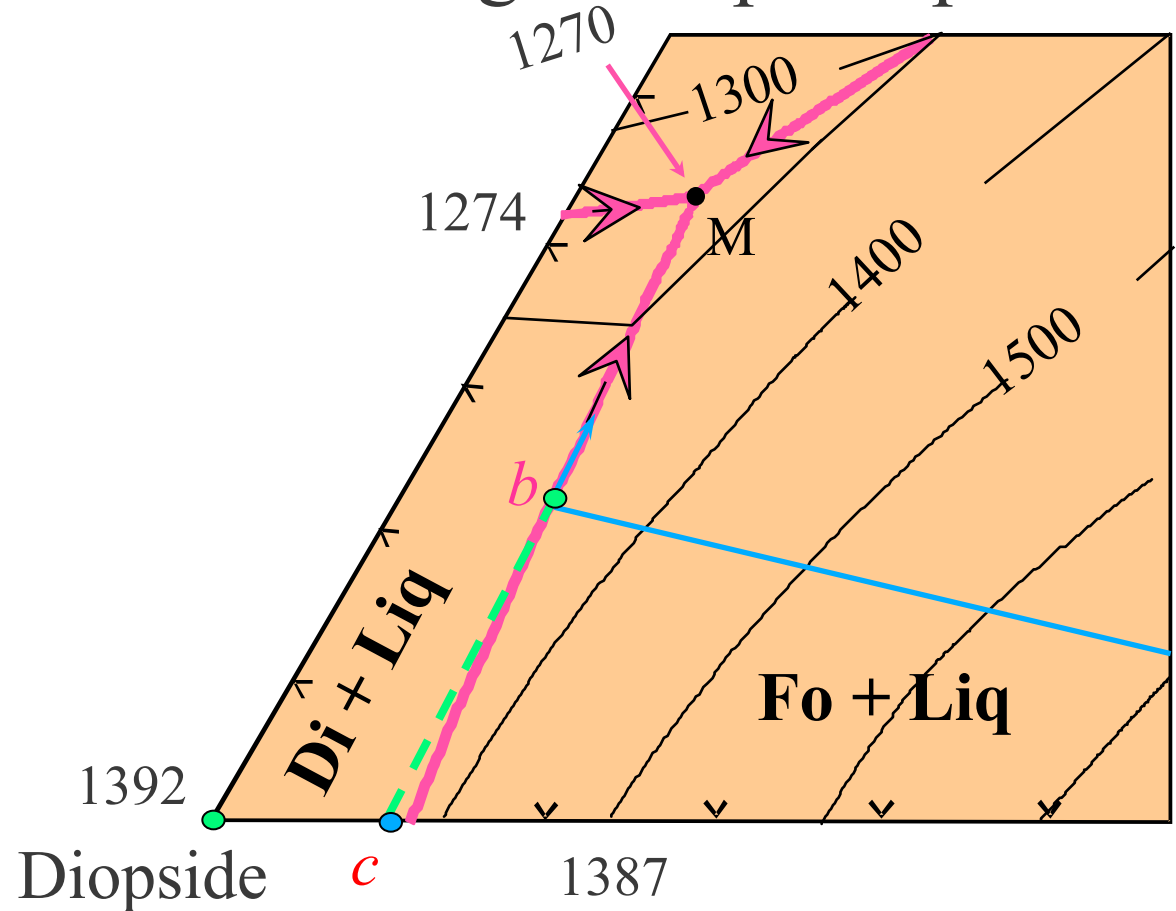

- New continuous reaction as liquid follows cotectic:

- Bulk solid extract

- Di/Fo in bulk solid extract using lever principle

◆ At 1300°C liquid = X

◆ Imagine triangular plane X - Di - Fo balanced on bulk a

$$\text{Liq/total solids} = \frac{\overline{a-m}}{\overline{\text{Liq-a}}}$$

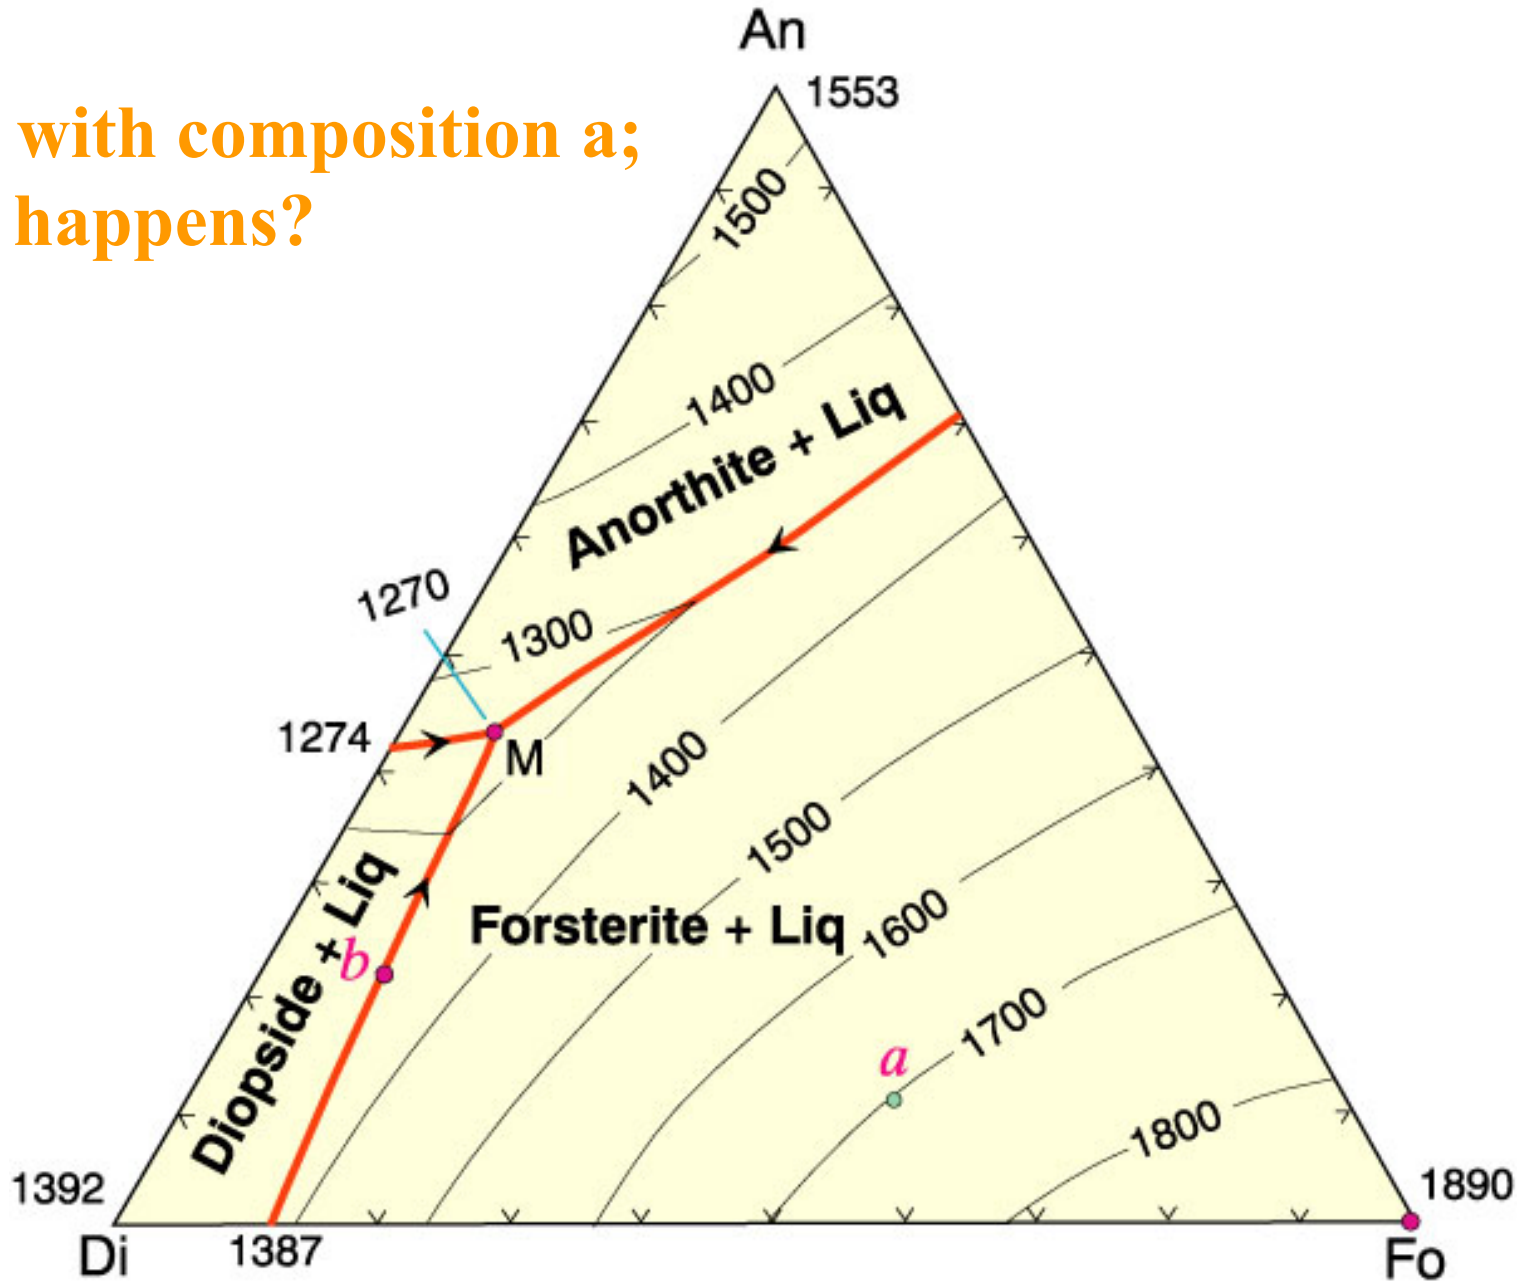

$$\text{total Di/Fo} = \frac{\overline{m-Fo}}{\overline{\text{Di-m}}}$$

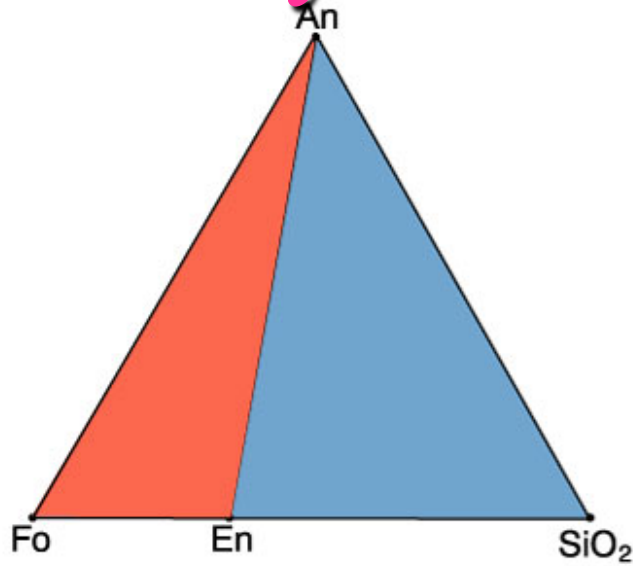

Partial Melting (remove melt):

Start with composition *a*;
what happens?

Ternary Peritectic Systems:

(at 0.1 MPa)

3 binary systems:

Fo-An eutectic

An-SiO₂ eutectic

Fo-SiO₂ peritectic

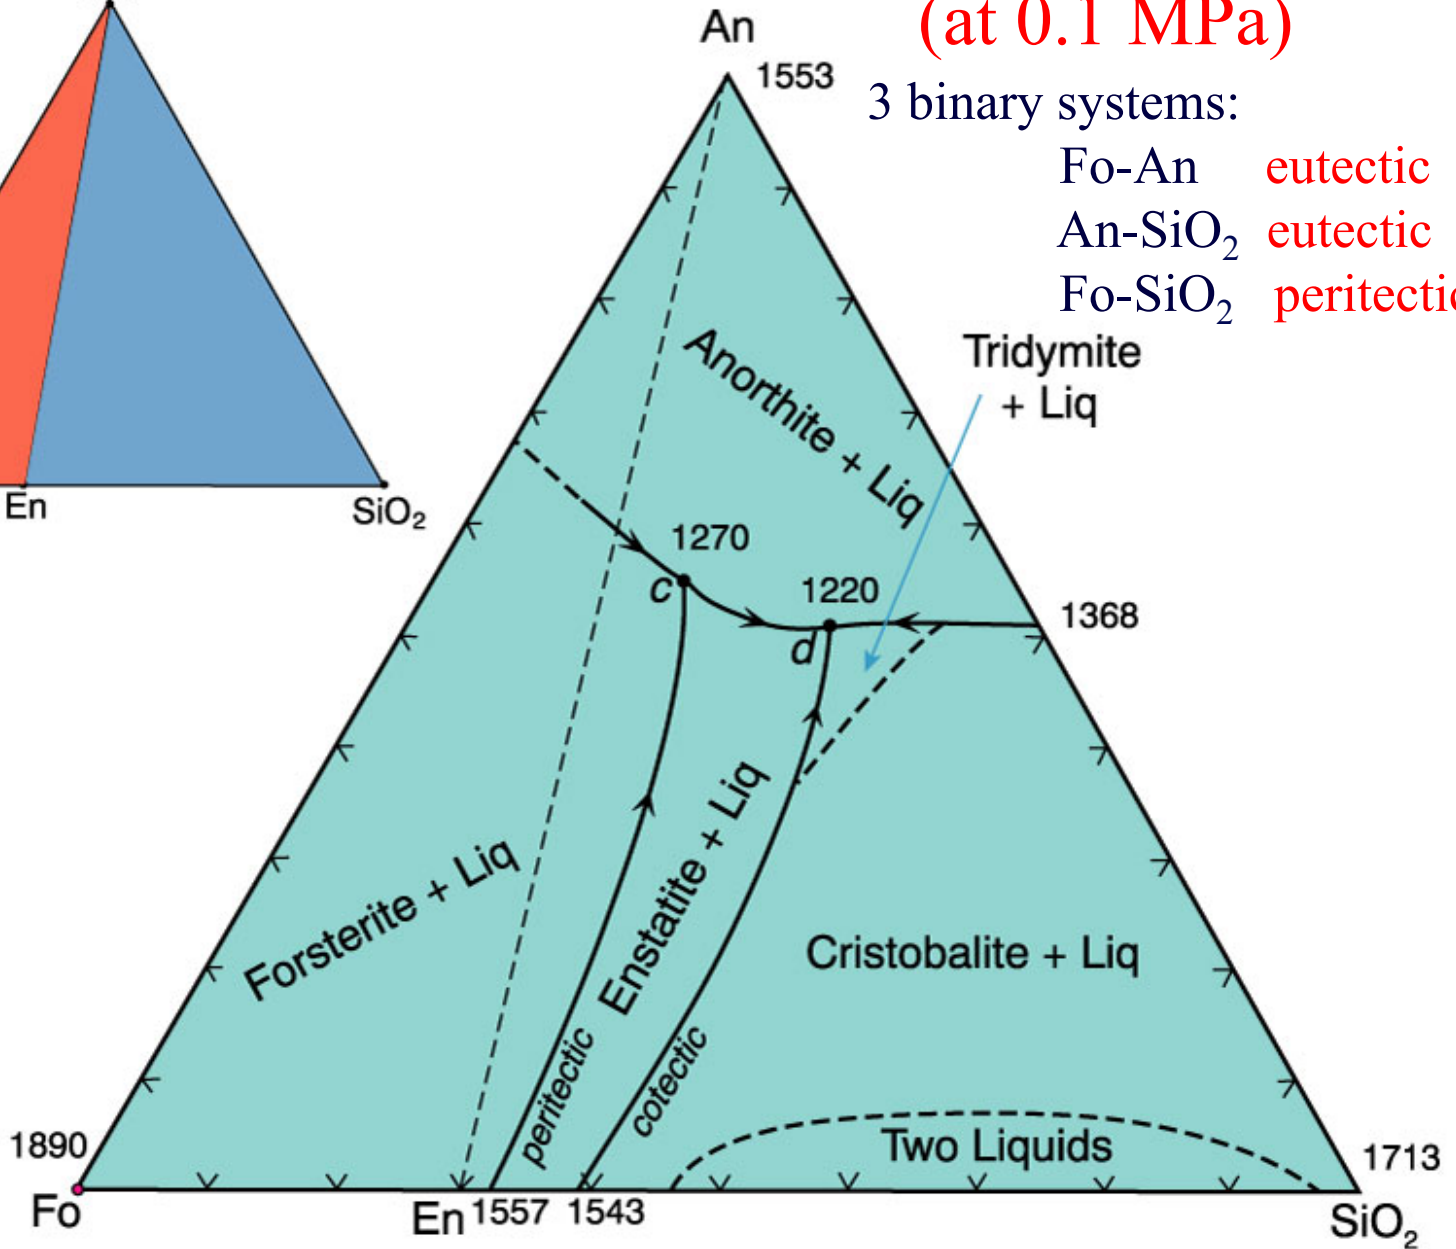

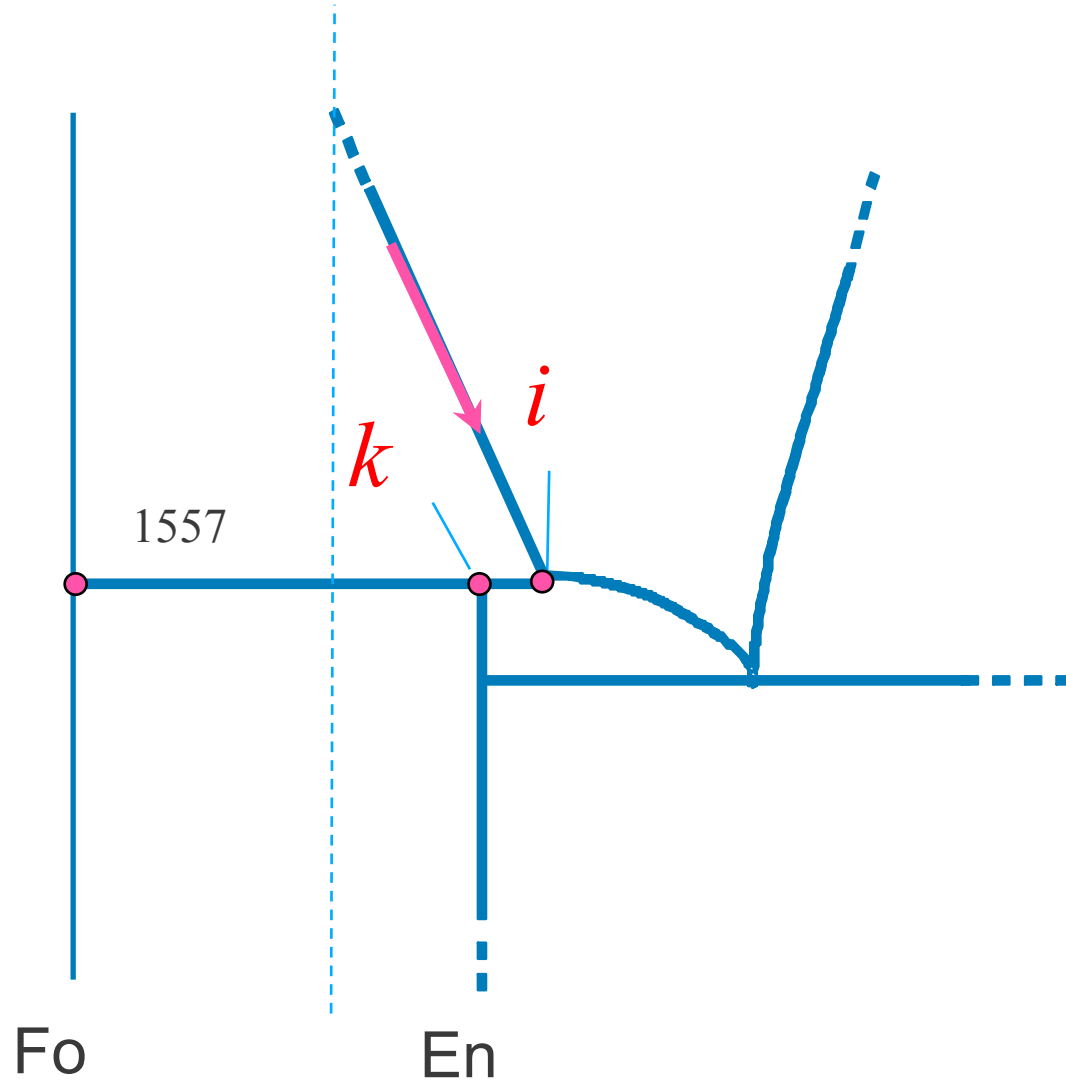

Figure 7.4. Isobaric diagram illustrating the cotectic and peritectic curves in the system forsterite-anorthite-silica at 0.1 MPa. After Anderson (1915) *A. J. Sci.*, and Irvine (1975) *CIW Yearb.* 74.

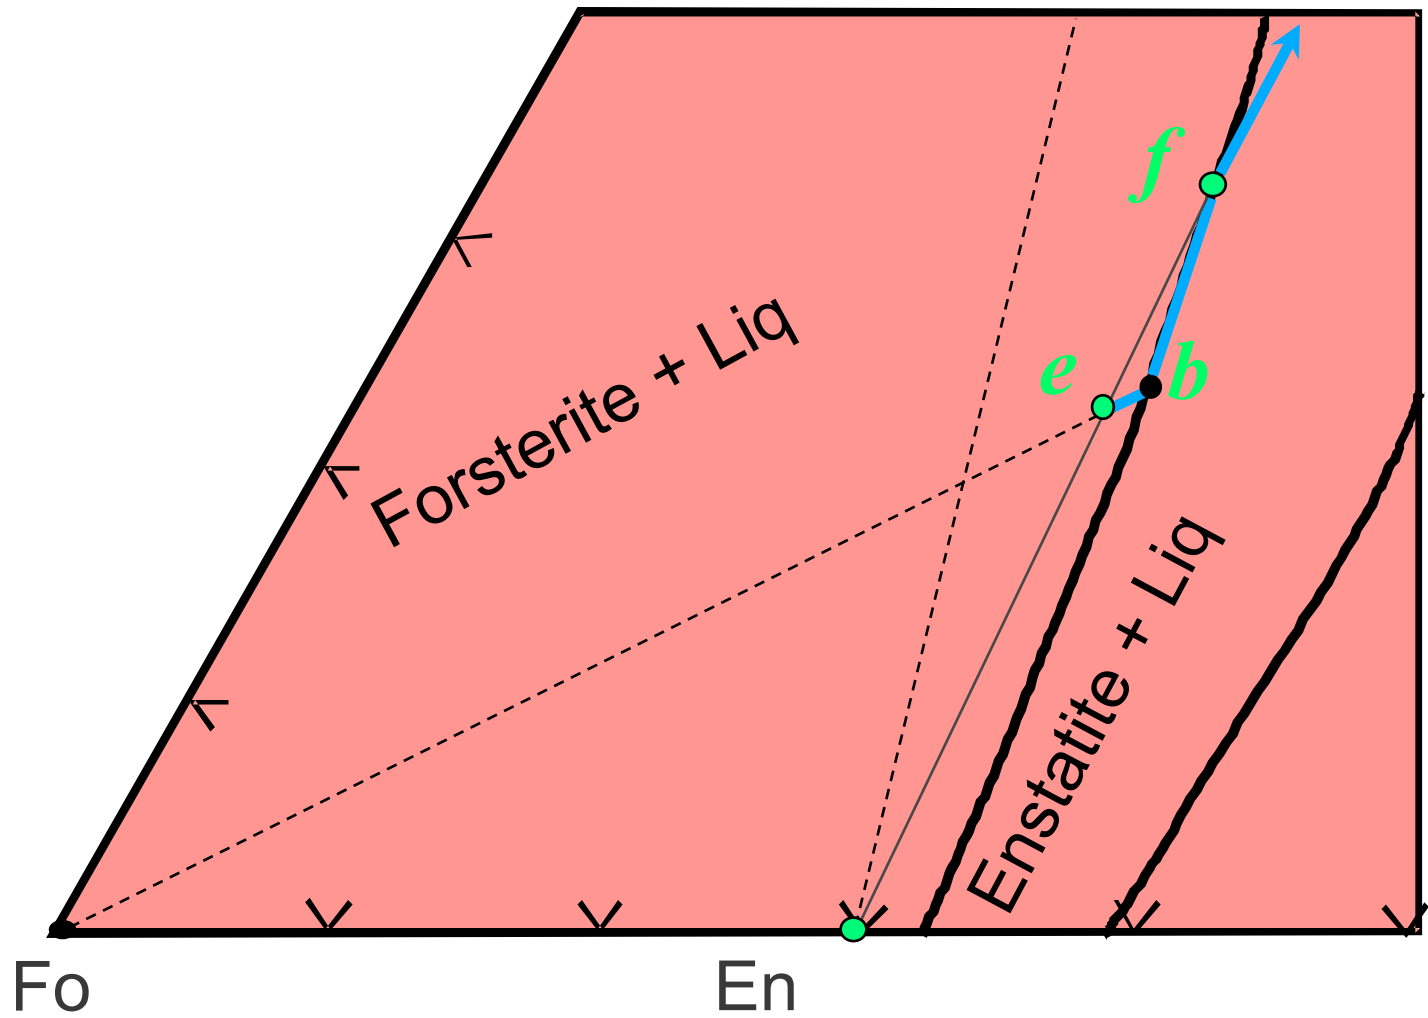

Works the same way as the Fo - En - SiO₂ binary

Diopside-Albite-Anorthite

Figure 7.5. Isobaric diagram illustrating the liquidus temperatures in the system diopside-anorthite-albite at atmospheric pressure (0.1 MPa). After Morse (1994), *Basalts and Phase Diagrams*. Krieger Publishers

Di - An eutectic

Di - Ab eutectic

Ab - An solid solution

Isobaric polythermal projection

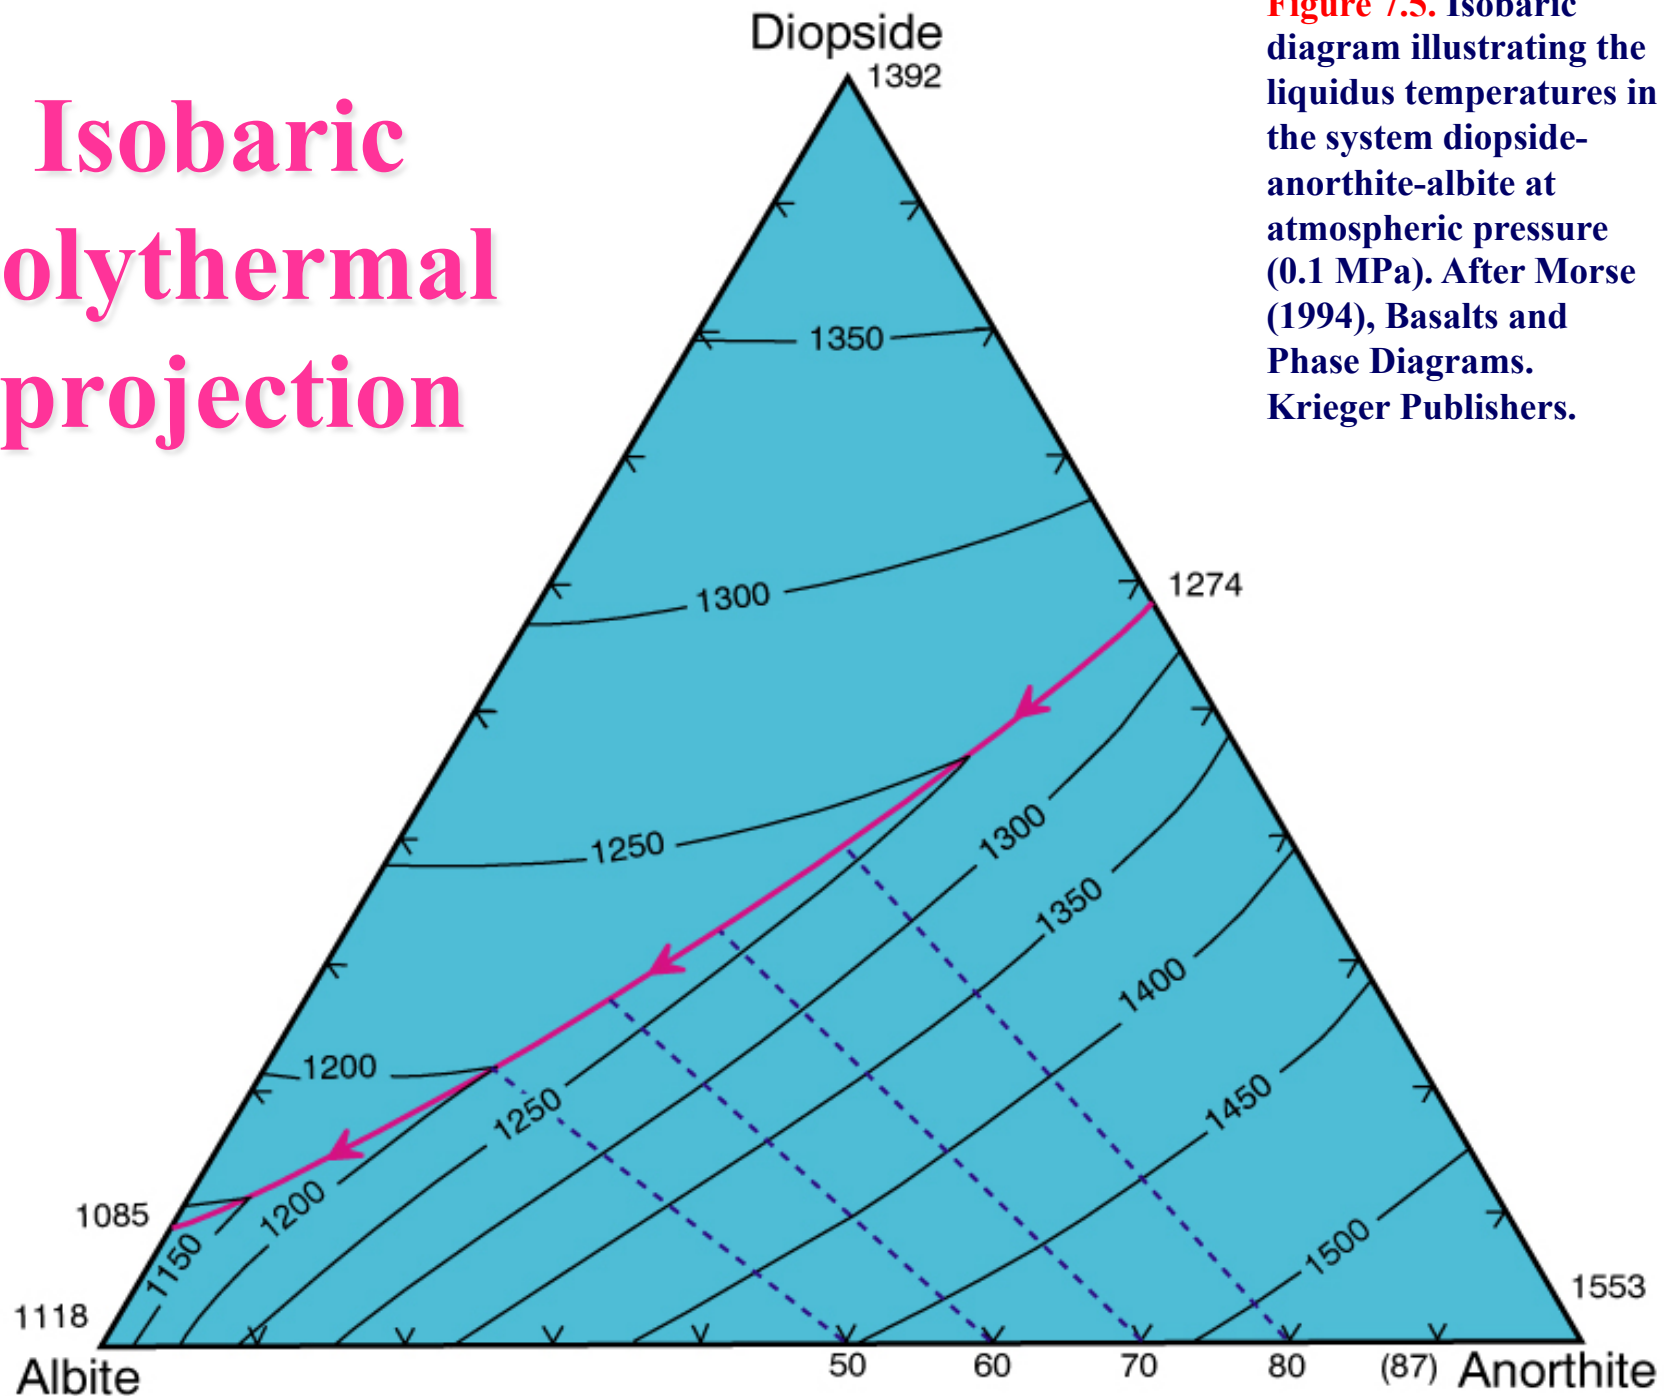

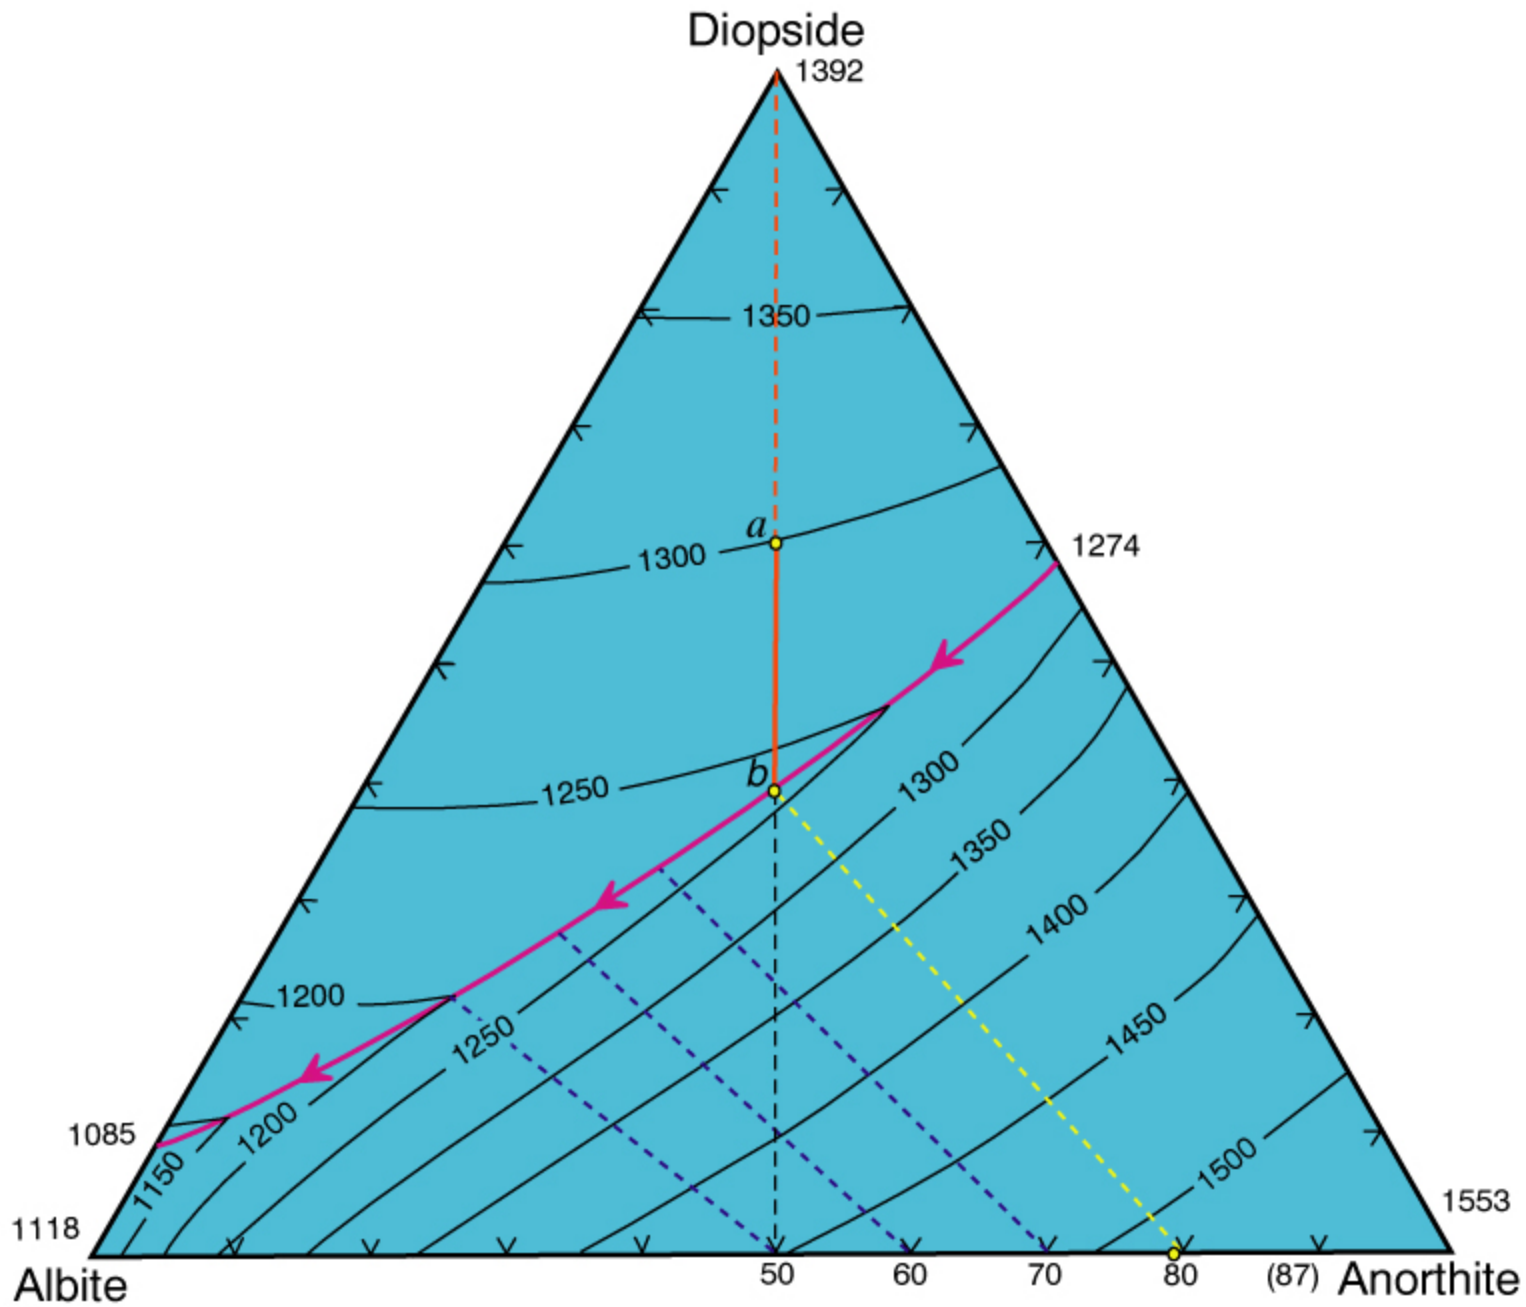

Figure 7.5. Isobaric diagram illustrating the liquidus temperatures in the system diopside-anorthite-albite at atmospheric pressure (0.1 MPa). After Morse (1994), *Basalts and Phase Diagrams*. Krieger Publishers.

Note:

Binary character is usually maintained when a new component is added

- ◆ **Eutectic behavior remains eutectic**
- ◆ **Peritectic behavior remains peritectic**
- ◆ **Solid solutions remain so as well**

Ternary Feldspars

Figure 7-10. After Carmichael *et al.* (1974), *Igneous Petrology*. McGraw Hill. Or

Ternary Feldspars

Trace of solvus
at three
temperature
intervals

Triangle shows coexisting
feldspars and liquid at
900°C

Figure 7.11. Winter (2010) An Introduction to Igneous and Metamorphic Petrology. Prentice Hall.

4 - Component Diagrams

Figure 7.12. The system diopside-anorthite-albite-forsterite. After Yoder and Tilley (1962). *J. Petrol.*

> 4 Components

Figure 7.13. Pressure-temperature phase diagram for the melting of a Snake River (Idaho, USA) tholeiitic basalt under anhydrous conditions. After Thompson (1972). Carnegie Inst. Wash Yb. 71

Bowen's Reaction Series

The Effect of Pressure

Eutectic system

Figure 7.16. Effect of lithostatic pressure on the liquidus and eutectic composition in the diopside-anorthite system. 1 GPa data from Presnall *et al.* (1978). *Contr. Min. Pet.*, 66, 203-220.

The Effect of Water on Melting

Dry melting: solid \rightarrow liquid

Add water- water enters the melt

Reaction becomes:

Figure 7.19. The effect of H₂O saturation on the melting of albite, from the experiments by Burnham and Davis (1974). *A J Sci* 274, 902-940. The "dry" melting curve is from Boyd and England (1963). *JGR* 68, 311-323.

Figure 7.20. Experimentally determined melting intervals of gabbro under H₂O-free (“dry”), and H₂O-saturated conditions. After Lambert and Wyllie (1972). *J. Geol.*, 80, 693-708.

Dry and water-saturated **solidi** for some common rock types

The more mafic the rock
the higher the melting
point

All solidi are greatly
lowered by water

Figure 7-21. H₂O-saturated (solid) and H₂O-free (dashed) solidi (beginning of melting) for granodiorite (Robertson and Wyllie, 1971), gabbro (Lambert and Wyllie, 1972) and peridotite (H₂O-saturated: Kushiro *et al.*, 1968; dry: Hirschman, 2000).

We know the behavior of water-free and water-saturated melting by experiments, which are easy to control by performing them in dry and wet sealed vessels

What about real rocks?

Some may be dry, some saturated, but most are more likely to be in between these extremes

- a fixed water content $<$ saturation levels
- a fixed water activity

The solubility of water in a melt depends on the structure of the melt (which reflects the structure of the mineralogical equivalent)

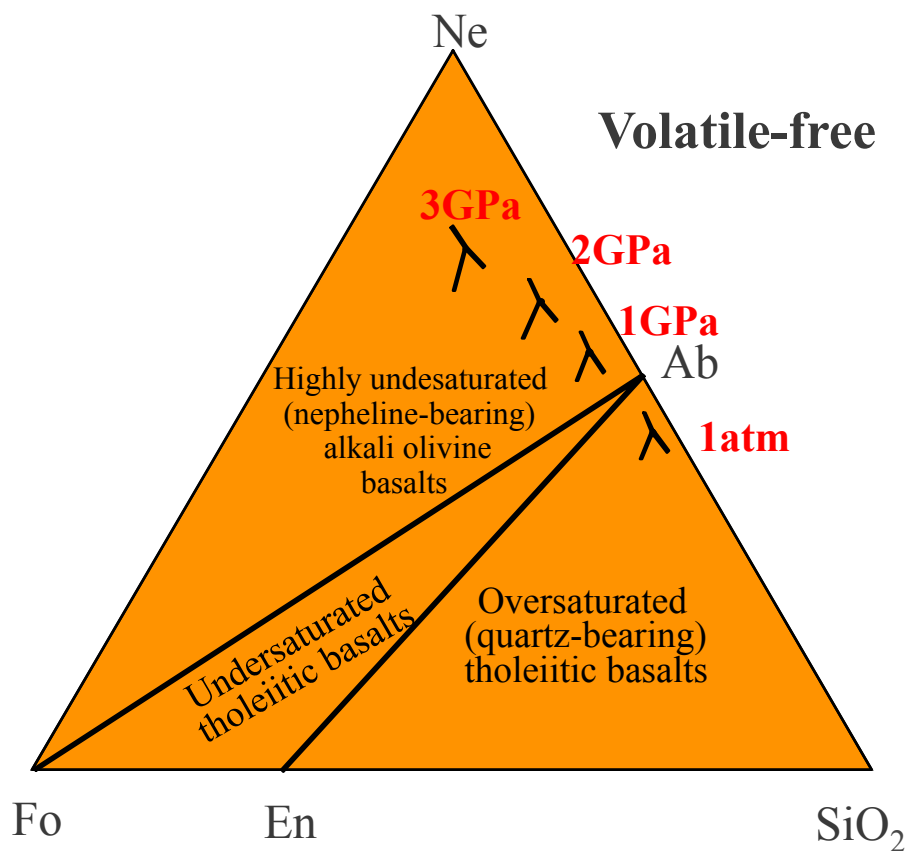

Figure 7.25. The effect of H₂O on the diopside-anorthite liquidus. Dry and 1 atm from Figure 7-16, $P_{H_2O} = P_{total}$ curve for 1 GPa from Yoder (1965). CIW Yb 64.

Effect of Pressure, Water, and CO₂ on the position of the eutectic in the basalt system

Increased pressure moves the ternary eutectic (first melt) from silica-saturated to highly undersat. alkaline basalts

Water moves the (2 GPa) eutectic toward higher silica, while CO₂ moves it to more alkaline types
